#### Water models / solvation

Andrew Torda, May 2010, strukt & sim

## Biggest effects of water

- electrostatic
- dynamic

#### Model types

- explicit
- implicit

Dynamic effects of water

# Dynamic effects of water

one lonely moving particle

- initial velocity  $\dot{x}_t$
- future velocity easy  $\dot{x}_{t+\delta t} = \dot{x}_t$
- energy? constant  $\frac{m\dot{x}^2}{2}$

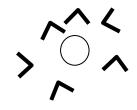

two particles? interacting?

- future velocity a bit more difficult
- easily bounded cannot be more than  $\underline{m_1\dot{x}_1^2 + m_2\dot{x}_2^2}$

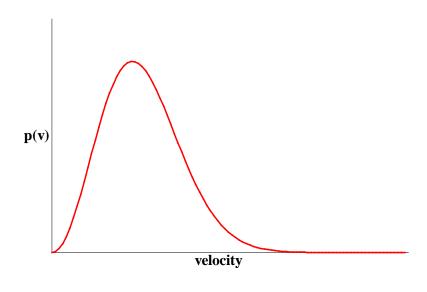

one particle in water...

# Velocities of particles in water

• lots of random interactions

- a small velocity?
- a big velocity?
- a probability distribution
- how does  $\dot{x}_t$  tell us about  $\dot{x}_{t+\delta t}$ ?
  - much less

# Modelling dynamic effects

#### Summary

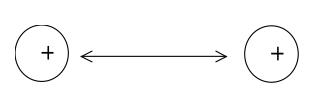

- solvent will add fluctuations
- makes us forget velocity faster

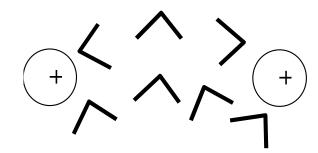

#### Can this be modelled?

- yes (in molecular dynamics simulations)
- not really a force field / energy topic
- add random fluctuations to velocities
- can be made to look like water

#### **Electrostatic effects of water**

- water molecules
  - not charged
  - polar
- interaction between charges very different if water in between
- details soon

# **Explicit water**

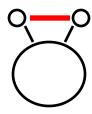

- earlier descriptions of proteins
  - a set of connected atoms
- extend to include water
- what does water look like?
  flexible angle

- what else has it got? charge
  - think about electron pair on "O"
- what is really important?

# Important features of a water model

Do we care about water internal dynamics?

- usually not
- make bonds rigid
- make angle rigid
  - treat as a bond

#### **Dimensions**

- protons are really small
- does water geometry matter?
  - usually not

## Charge

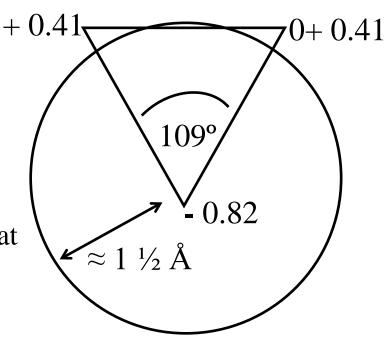

most important

## A useful explicit water model

- 3 charges
- 1 Lennard-Jones radius
- 3 masses why?
  - only for molecular dynamics
- 3 bonds (completely rigid)
- has a name "SPC"
- what can it do?
  - diffusion, density, compressibility, heat capacity
  - dielectric constant
  - solvation energies ?
- perfect?
  - no
    - add polarisation, bonds, bond angles, offset charge from mass

# **Explicit water + protein**

#### Protein water interactions

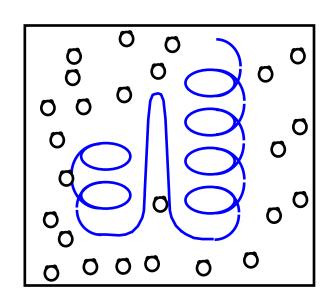

- via charge
- via Lennard-Jones term  $(r^{-12} \text{ and } r^{-6})$
- Only average properties are interesting
- useful only in simulations (MC, MD)

#### What is neat

- automatically incorporates
  - dynamic effects
  - electrostatics

#### **Problems**

- very very expensive
- typical simulation 10<sup>3</sup> protein atoms
- 10<sup>4</sup> solvent atoms

# worst case for proteins + water

#### Imagine a world with no cutoffs for interactions

- scales as  $O(n^2)$
- adding water takes 5 or 10 times as many atoms
- takes 25 or 100 times as much CPU time

#### Even worse

• proteins move more slowly in water (viscosity)

#### What to do?

look for cheaper model

## **Cheaper water models**

- Do we really need dynamic effects of water?
  - maybe not
    - only want energies
    - only care about structures
  - or
    - model with a random force
- then look for model which gets most essential aspects of water
  - electrostatics
    - distance dependent dielectric
    - reaction field
    - surface area methods

## Distance dependent idea

Bare charges interacting 
$$+ \longleftrightarrow U(r_{ij}) = \left(\frac{1}{4\pi\varepsilon_0}\right) \frac{q_i q_j}{r_{ij}}$$

With solvent 
$$+$$
  $U(r_{ij})$  changes less than  $\frac{q_i q_j}{Dr_{ij}}$ 

Net effect?

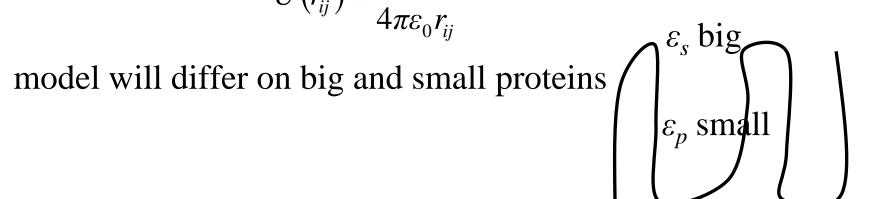

- water is very polar and tends to orient itself around charges
- as if the water "screened" the charges (makes them smaller)

# Distance dependent dielectric implementation

- invent approximation  $D_{eff} = r_{ij}$  then  $U(r_{ij}) \approx \frac{q_i q_j}{D_{eff} r_{ij}} \approx \frac{q_i q_j}{r_{ij}^2}$
- is this physics?
  - no
- does it work?
  - a bit (ugly)
  - little real physical basis
- water does not behave so simply
- fundamental problem...

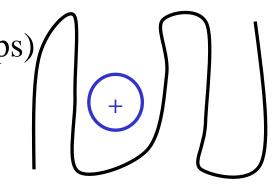

# Fundamental problem with distance dependent D

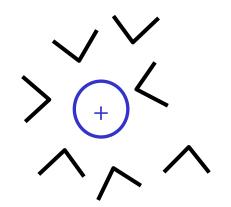

- if we rely on distance dependent dielectric constant
  - assume one 'fix' works everywhere (not true)
- think of formula

#### Reaction field idea

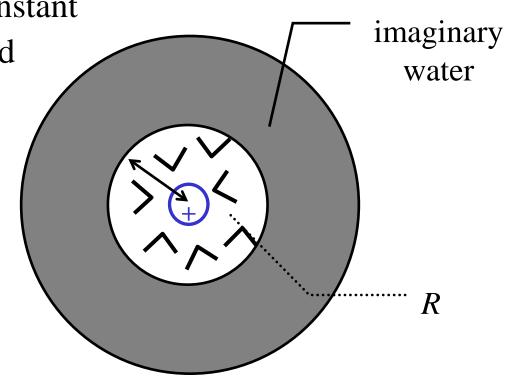

- different problem to before
- charge in a protein (lots of neutral CH groups)
  - not much happens
- particle in water
  - what does the water do?
  - tends to orient
  - lots of q<sup>+</sup>q<sup>-</sup> interactions
    - much better energy
  - is this like a force?
    - yes, think -dU/dr
  - can this be modelled?

# interaction with imaginary solvent

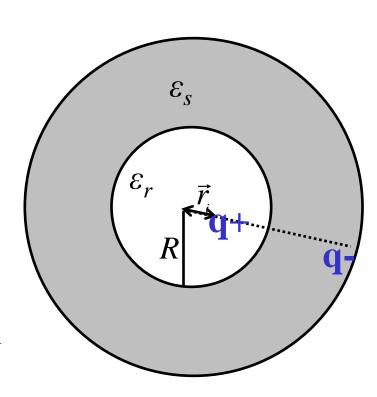

- think of particle interacting with distant water molecules
- our charge interacts with them all but
  - if they are far away (big R) less important
  - depends on dielectric constant
  - inside white region  $\varepsilon_r$  and
  - grey region  $\varepsilon_s$
- within white region
  - treat atoms with a correction
- grey region
  - treat as continuum

# Realistic picture infinite continuum R=25 Å cutoffs 10 to 12 Å

# Reaction field / image charge formula

- as if we interact with an "image" charge
- size  $q_{im} = -\frac{\left(\varepsilon_{s} \varepsilon_{r}\right)}{\left(\varepsilon_{s} + \varepsilon_{r}\right)} \frac{q_{i}R}{r_{i}}$
- location  $\left(\frac{R}{r_i}\right)^2 \vec{r}_i$
- near middle
  - $R >> r_i$
  - image far away
- near boundary
  - imaginary solvent important
  - strong (favourable) interaction
- important result
  - we have modelled the happiness of a charge in solution
  - charges happiest on outside of protein

# Reaction fields and pairs

- charge  $q_i$  interacts with water
- water responds
- $q_i$  feels effect of water
- no longer  $U(r_{ij}) = \frac{q_i q_j}{4\pi \varepsilon_0 r_{ij}}$
- instead,  $U(r_{ij}) = \frac{q_i q_j}{4\pi\varepsilon_0 r_{ii}} \cdot f(q_i, q_j, \text{distances to center, ...})$

## Simpler ways to model solvent

#### Problem with real physics

- if you use this model, you are obliged to use
  - real charges, real coordinates...
- parameters not perfect
- hard to rationalise repairs

#### Many effects simultaneously

- charges interacting with water dipoles
- loss of water water interactions
- change of solvent entropy
- change of solute entropy?

#### Different approach

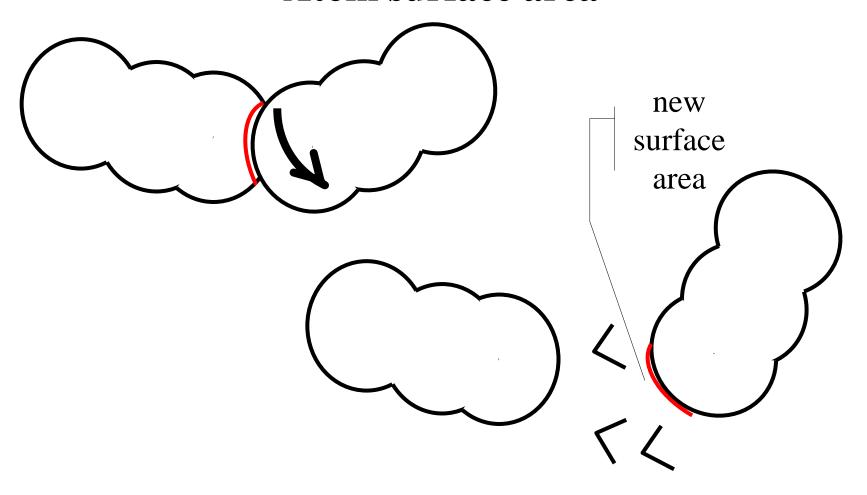

• less rigorous models

# Basis of quick water model

## Philosophy

- I can not model water properly
- find a very general way to incorporate effects
- Water makes some atoms happy
- Others do not care too much
- Find some very general way to include water effects
  - whether they are favourable / unfavourable
- what is easiest way to think about water influence ?

## Atom surface area

- simple model
  - for each atom, energy depends on surface area

# Formalising SASA model

- Solvent accessible surface area (SASA)
- for every atom, i  $G_i^{solv}(\vec{r}_i) = \gamma_i A_i(\vec{r}_i)$
- G because we no longer have a pure potential energy
- $G_i^{solv}(\vec{r}_i)$  because the energy term depends on coordinates
- $\gamma_i$  is a specific parameter for each kind of atom
  - for O, N will be negative
  - for CH, CH<sub>2</sub>, CH<sub>3</sub> will be positive or near zero
- area,  $A_i$ , has to be calculated

#### **Problems**

- $A_i$  is difficult to calculate
  - use approximation
- $\gamma_i$  not easy to estimate

# Example SASA calculation<sup>1</sup>

- classical atomistic force field
- distance dependent dielectric
- two  $\gamma_i$  parameters,  $\gamma_{C.S} = 0.012$  and  $\gamma_{O.N} = -0.060$  kcal mol<sup>-1</sup>

#### Results

- better than in vacuo
  - deviation from known structure during simulation
  - not too many H-bonds formed
  - radius of gyration ? (how big is protein)
- why do they appear OK? why only two  $\gamma_i$ ?
  - not tested in detail
  - worst problems fixed

#### summary

- Explicit water is best, but expensive
- We have not discussed dynamic effects
- distance dependent dielectric +
  - SASA style models
  - complementary
- many variations
  - surface accessible volume
  - more  $\gamma_i$  parameters
  - add in reaction field for better long range electrostatics
- changes and flaws in one parameter are hidden by others
