### Monte Carlo and MD simulations

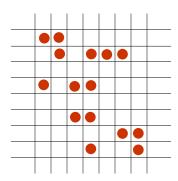

Andrew Torda, April 2013 strukt und sim

## What we observe in any system?

averages of observables (pressure, energy, density)
 Given enough time system will visit all states

time

random hopping

My observable A

$$A_{obs} = \frac{1}{b-a} \int_{a}^{b} A_{t} dt$$

$$A_{obs} = \frac{1}{N_{obs}} \sum_{i=1}^{N_{obs}} A_i$$

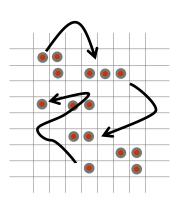

# Time and space averages

If we believe 
$$A_{obs} = \frac{1}{N_{obs}} \sum_{i=1}^{N_{obs}} A_i$$

then

$$A_{obs} = \sum_{j}^{states} p_{j} A_{j}$$

$$\equiv \langle A \rangle$$

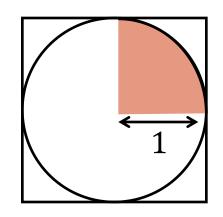

- $\langle A \rangle$  is ensemble average and usually  $\bar{A}$  is time average
- if sample with correct probability, we can find  $A_{obs}$
- order of visiting states does not matter

### **Monte Carlo**

How to calculate  $\pi$  with random numbers

$$\frac{points_{red}}{points_{square}} = \frac{1/_{4}\pi r^{2}}{\text{area in square}}$$

$$\pi = 4 \frac{points_{red}}{points_{square}}$$

$$n_{square}$$
++
if  $((x^2+y^2) < 1)$ 
 $n_{red}$ ++
print  $4 \frac{n_{red}}{n_{square}}$ 

# Generating distributions / Monte Carlo

Generating points in a circle? (generating function)

$$p_{in\_circle} = \begin{cases} 1 & x^2 + y^2 \le 1 \\ 0 & x^2 + y^2 > 1 \end{cases}$$

 we could work out the area of a circle (integrate) by picking random numbers

What does Monte Carlo simulation mean?

- generating points according to some distribution to find an average or integral
- what is our distribution in physical systems?
  - Boltzmann distribution

### Monte Carlo and Boltzmann distributions

Boltzmann probability distribution

$$p_i = \frac{e^{\frac{-E_i}{kT}}}{\sum_j e^{\frac{-E_j}{kT}}}$$
 often written as  $p_i = \frac{e^{\frac{-E_i}{kT}}}{Z}$ 

- if we could generate this distribution, we could reproduce most properties of a system
- leads to a scheme (not possible)

# correct, but not practical scheme

```
while (not happy)
   generate configuration \mathbf{r}_i (conformation of protein, ...)
                                    (number between 0 and 1)
   calculate p_i
   generate random number x
                                                                        p_{i} = \frac{e^{\frac{-E_{i}}{kT}}}{\sum_{i} e^{\frac{-E_{j}}{kT}}}
   if (x < p_i)
         accept \mathbf{r}_i
   else
         reject \mathbf{r}_i
```

- result? a set of  $\mathbf{r}_i$  with Boltzmann distribution
- problem? we do not know  $\sum_{j} e^{\frac{-E_{j}}{kT}}$

## a better scheme

We cannot generate points from 
$$p_i = \frac{e^{\frac{-E_i}{kT}}}{\sum_j e^{\frac{-E_j}{kT}}}$$

What if we have two configurations?

$$\frac{p_i}{p_j} = \frac{e^{\frac{-E_i}{kT}}}{Z} \frac{Z}{e^{\frac{-E_j}{kT}}}$$

$$=\frac{e^{E_j-E_i}}{kT}$$

$$=e^{\frac{-\Delta E}{kT}}$$

### a better scheme

$$\frac{p_i}{p_j} = e^{\frac{-\Delta E}{kT}}$$

If we have one configuration to start

- we can work out the relative probability of a second
- convenient convention
  - going from old $\rightarrow$ new  $\Delta E < 0$ 
    - $E_{new} E_{old} < 0$  energy is better / more negative

# **Metropolis Monte Carlo**

• generating a distribution

$$\frac{p_i}{p_j} = e^{\frac{-\Delta E}{kT}}$$

- if  $\Delta E < 0$ , new is likely (more than 1)
- if  $\Delta E > 0$ , old is  $p_{new}$  is possible
- generate starting configuration  $\mathbf{r}_{o}$

```
while (not happy)  \text{generate } \mathbf{r}_{new}   \text{calculate } E_{new} \text{ and } \Delta E   \text{if } \Delta E < 0   \text{set } \mathbf{r}_o \text{ to } \mathbf{r}_{new}   \text{else}   \text{x = rand } [0:1]   \text{if} \left( x \leq e^{-\Delta E_{kT}} \right)
```

set  $\mathbf{r}_o$  to  $\mathbf{r}_{new}$ 

- what if  $\Delta E$  slightly > 0?
  - 0.000000001
- what if  $\Delta E = 10^6$  ?
- small uphill moves are OK
- bigger moves are less likely

# **Properties of Monte Carlo**

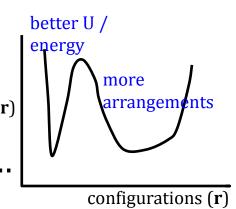

The set of  $\mathbf{r}_o$  is a valid distribution (ensemble)

• for some property *A* 

$$A_{obs} = \langle A \rangle = \frac{1}{N_{visited}} \sum_{i}^{N_{visited}} A_i$$

• A could be density, structural property, E, ...

• only works for one temperature *T* 

- look at picture.. could I calculate entropy / free energy?
  - for simple systems

# **Equilibrium**

MC results (observables / averages)

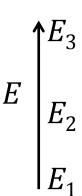

- only for system at equilibrium
- Simulations generate system at equilibrium

What happens for a system out of equilibrium?

- Toy system with 3 states
- for some *T*, at equilibrium

• 
$$p_1 = \frac{5}{8}$$
  $p_2 = \frac{1}{4}$   $p_3 = \frac{1}{8}$ 

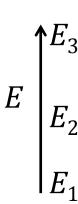

• if I have 80 copies of the system, most are in state<sub>1</sub>

# Reaching equilibrium

System wants 
$$p_1 = \frac{5}{8}$$
  $p_2 = \frac{1}{4}$   $p_3 = \frac{1}{8}$   $50:20:10$ 

- start it with 5:70:5
- all moves 2→1 are accepted (large flux)
- the flux from  $1 \rightarrow 2$ 
  - 1→ 2 moves are not always accepted
  - there are less particles in state<sub>1</sub>
- moving to equilibrium depends on
  - population
  - probability

### **Detailed balance**

For any two states (state<sub>i</sub> and state<sub>j</sub>)

Flow  $i \rightarrow j$  must equal  $j \rightarrow i$ 

otherwise?

Flow  $i \rightarrow j$  depends on

- population  $N_i$
- probability  $\pi(i \rightarrow j)$

Detailed balance

$$N_i \pi(i \rightarrow j) = N_j \pi(j \rightarrow i)$$

• detailed balance must apply for any pair *i*, *j* 

all textbooks use  $\pi$  for probability here

# **Ergodic**

## Assumptions

- I can do integrals because
  - I will visit every state
  - I can calculate  $p_i$  for all states
- I will visit every state

## alternatively

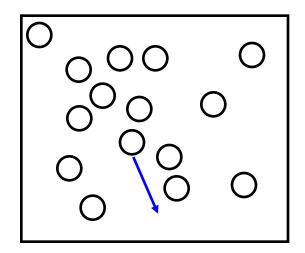

## For any i, j

- $\pi(i \rightarrow j) > 0$
- may require a finite number of steps:  $i \rightarrow k \rightarrow m \rightarrow j$
- must be satisfied

## **Moves**

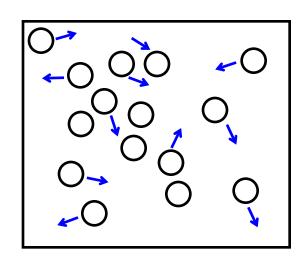

### version 1

- decide on  $r_{max}$
- pick a particle at random
- pick random  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$ 
  - $0 < \Delta a < r_{max}$
- apply move
- accept / reject move

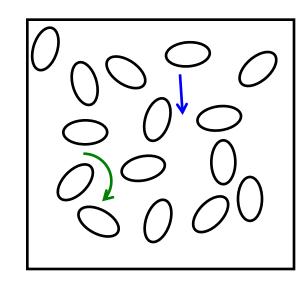

#### version 2

- decide on smaller  $r_{max}$
- foreach particle
  - pick random  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$ 
    - $0 < \Delta a < r_{max}$
- apply move
- accept / reject

### **Moves**

- both kinds of move OK
- note
  - "accept / reject"
- more generally,
  - how big is  $r_{max}$ ?
  - big
    - system moves faster
    - more moves rejected
- what if my particles are not spheres?
  - rotations also necessary
- time has no meaning

# **Bonded systems**

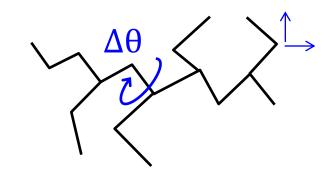

Protein (lipid, polymer, ..)

#### Random $\Delta x$ ?

- nearly all will stretch a bond
  - high energy : rejected move
- only feasible method
  - random rotations  $\Delta\theta$

## In general

- most kinds of simple moves OK
- must maintain detailed balance, ergodicity
- question of efficiency
  - high rejection rate means lots of wasted calculations

# More moves - N particles

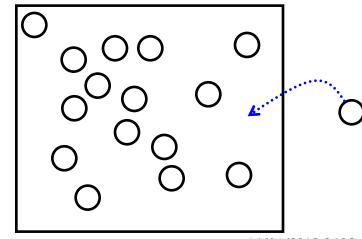

$$\frac{p_{new}}{p_{old}} = e^{-\Delta E/kT}$$

I have defined temperature

- and  $N_{particles}$  and V
- called NVT simulation

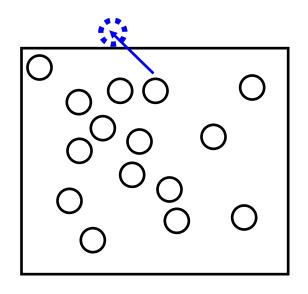

Vould I have varied something else?

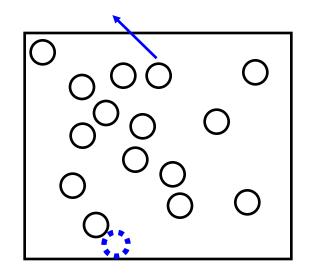

- what if I tried to put particles in / take out?
  - sometimes energy ↑sometimes↓
- system will fluctuate around  $\langle N \rangle$
- this would not be NVT

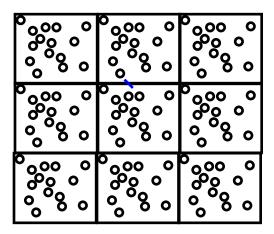

# **Periodic Boundary Conditions**

Technical point relevant to gases, proteins in water...

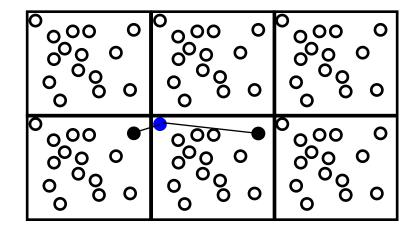

Behaves like an infinite system

### **Infinite interactions?**

## Neighbours of blue particle

- only use the nearer
- not really an infinite system
- volume defined by box

### **Problems with Monte Carlo**

```
while (not happy)

propose move

accept / reject move
```

### Small steps?

system moves slowly: long time to visit all states

## Big steps?

- calculate energy
- reject move
  - no progress, wastes time

# **Dense Systems and Monte Carlo**

#### Random moves?

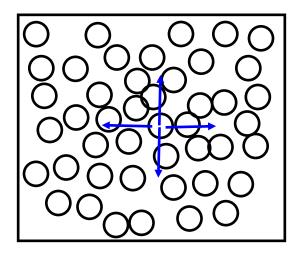

most moves rejected

## Dense systems?

- liquids
- proteins, polymers, ...

#### Solutions

- cleverer MC moves (later)
- MD

# Why do molecular dynamics simulations?

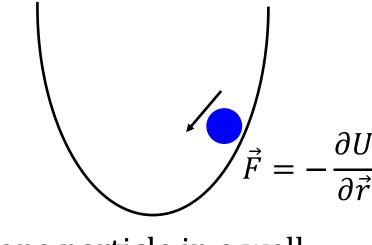

#### Real world

- box of gas, molecule in space, protein molecule in water
- atoms hit each other,
  - share energy, box expands/contracts, ...
  - soon reaches equilibrium
  - visits low energies (often), high energies (less often)
  - visits entropically favoured regions
- we stick in a thermometer
- measure density, ...

#### What have the atoms done?

- feel forces and move
- an MD simulation just copies this

# What do we expect? Molecular Dynamics

one particle in a well

Unlike MC, particles have kinetic energy  $E_{kin}$ 

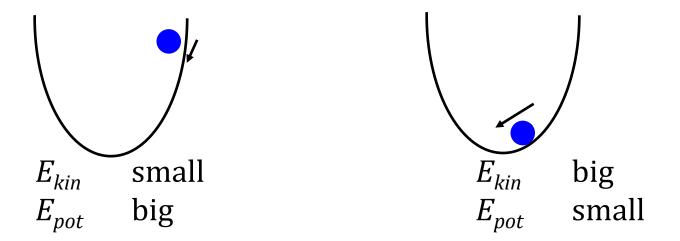

# Kinetic and potential energy

Our system is isolated (no work done)

*E* tot never changes

conserves energy (no work done on system)

$$E_{tot} = E_{pot} + E_{kin}$$

For one particle  $E_{tot} = E_{pot} + E_{kin} = \text{constant}$ 

# **Lots of particles**

## Particles hitting each other

- exchanging energy
- Total system
- conserves energy

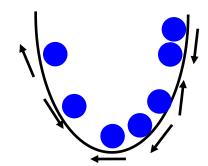

### One particle?

• per particle energy no longer conserved (may gain or lose)

## Many particles

- distribution of velocities
- distribution of potential energies

## Boltzmann distribution in real world

One version of real world (N, V, T)

- constant number of particles, volume, temperature
- today  $E = E_{kin} + E_{pot}$
- *Z* is partition function
- earlier  $Z = \sum_{i} e^{\frac{-\Delta E_i}{kT}}$

But now we have kinetic energy  $E_{kin}(\boldsymbol{p})$ 

- where  $\boldsymbol{p} = m\dot{\boldsymbol{x}}$ 
  - potential energy  $E_{pot}(\mathbf{r})$
- if we write in continuous form ...

### **Partition function for MD**

Usually write  $H(\mathbf{p}, \mathbf{r}) = E_{kin}(\mathbf{p}) + E_{pot}(\mathbf{r})$ 

• "Hamiltonian"

All the states are defined by all possible momenta and coordinates

• sum over these:  $Z(N, V, T) \propto \int d\mathbf{p} \int d\mathbf{r} \, e^{\frac{-H(p,r)}{kT}}$ 

often see  $\mathcal{H}(\mathbf{p}, \mathbf{r})$  or  $\mathcal{H}(\mathbf{\Gamma})$ 

### **MD Method**

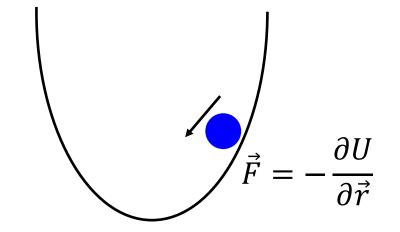

For any particle we can calculate forces

Newtons law

F = ma often better written  $\vec{\ddot{x}} = \vec{F}m^{-1}$ 

If we know acceleration

- we can get velocity
   from velocity
- can get coordinates

averaging, sampling,

# **Starting system**

#### Initial coordinates

- protein model
- protein from protein data bank (PDB)
- protein + proposed ligand
- box of liquid

#### Do initial coordinates matter?

- in principle: no infinitely long simulation visits all configurations, reaches equilibrium
- in practice: yes
  - bad examples
    - no simulation is long enough to predict protein conformation
  - take water configuration and run at ice temperature

### **Initial velocities**

First consider temperature – reflects kinetic energy

$$\left\langle \frac{1}{2} m v_{\alpha}^2 \right\rangle = \frac{1}{2} kT$$

where  $v_{\alpha}^2$  could be  $v_x$ ,  $v_y$ ,  $v_z$  leads to definition

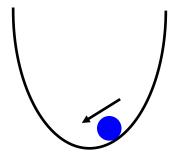

$$T(t) = \sum_{i=1}^{N} \frac{m_i v_i^2(t)}{k N_f}$$

- where  $N_f$  is number degrees of freedom  $\approx 3N$
- we could use this to get initial velocities  $\langle v_{\alpha}^2 \rangle = \frac{kT}{m}$

### **Initial velocities**

### Would one $\langle v^2 \rangle$ be OK?

- not very good
  - $E_{kin}$  correlated with  $E_{pot}$

#### Either

- use more sophisticated distribution
- do not worry
  - system will go to equilibrium
    - velocities will reach sensible values

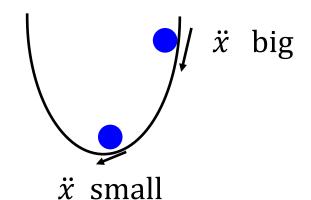

# **Getting new velocities / coordinates**

### constant acceleration

$$x_t = x_0 + vt + \frac{1}{2}at^2$$

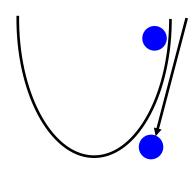

or

$$x_t = x_0 + \dot{x} + \frac{1}{2}\ddot{x}t^2$$

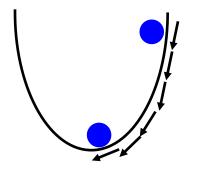

#### OK for constant acceleration

try to use formula to predict future time

big ∆t / step big error

small  $\Delta t$  / step small error slow

# Fundamental problem with integration

- We want to use big  $\Delta t$  (speed)
- We must use small  $\Delta t$  (accuracy)

All  $\Delta t$  will give us some error

numerical integration is never perfect

How small is  $\Delta t$ ?

- depends on fastest frequency / steepest walls in energy
  - usually bonds
- for proteins at room temperature
  - $\Delta t \approx 1$  fs (femtosecond  $10^{-15}$ s)
- high temperature  $\Delta t$  should be smaller

## Practical integrators

remove velocity – slightly more sophisticated

# **Noise and heating**

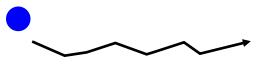

#### General rule

- noise heats the system
- formally difficult to prove
- $E_{kin} = \frac{1}{2} mv^2$ 
  - no kinetic energy

 $igchtharpoonup \mathcal{L}$   $E_{kin}$  due to noise

‡extra velocity

### **Noise-free Simulation**

Energy conservation : Absolute rule  $E_{pot} = f(\mathbf{r})$ 

- no time component
- invariant under translation, rotation

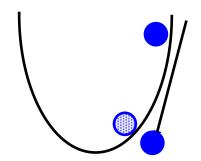

When violated?

• (r) does not change, but  $E_{pot}$  changes:  $E_{tot}$  changes

## **Noise Sources**

## Integrator

- coordinates do not match velocity  $E_{kin}$  wrong:  $(E_{kin} + E_{pot}) \neq \text{constant}$

energy not conserved

#### Numerical noise

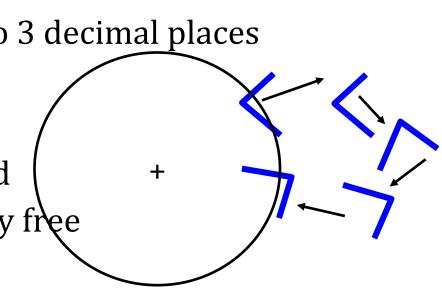

- $E_{pot} = f(\mathbf{r})$
- initial coordinates (r) quoted to 3 decimal places
- really less accurate

#### Cutoffs

- within cutoff rotation restricted
- outside cutoff rotation suddenly free

### Result

heating

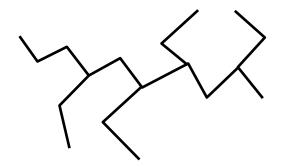

# **Equilibrium**

## Remember MC story

system not at equilibrium? eventually equilibrates

### MD

- start in high energy  $E_{pot}$
- $E_{pot}$  converted to  $E_{kin}$

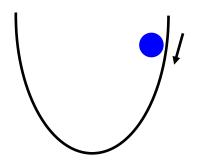

Some high energy conformation

- relaxes
- $E_{pot}$  converted to  $E_{kin}$

## MD system will not

- really find low energy
- known temperature

## MD in a closed system

An isolated molecule should not lose energy

A repeated box will not lose energy

- Formally system is
  - NVE (constant  $N_{particles}$ , volume, energy)

<b>0</b> 0000	0 0 0 0 0 0 0	0 0 0 0 0 0
0 0 0 0 0 0 0		0 0 0 0 0 0
0 0 0 0 0 0 0	0 0 0 0 0 0	0 0 0 0 0 0

#### **Problems**

- we want to set the temperature of the system
- we may have noise / heat creating energy

#### Cure

thermostat

### **Bath**

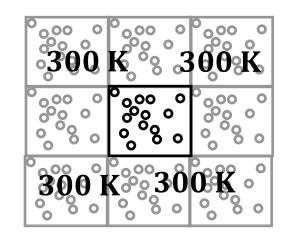

imagine infinite bath at desired temperature

- heat will flow in or out
- at equilibrium no flow of heat
  - maybe removal of noise/heat

How to implement? Many ways

### Occasionally:

- 1. introduce a fake particle desired temperature / collide
- 2. pick a particle at random / give average *v* for temperature
- 3. Easy method –weak coupling...

# **Weak Coupling**

Remember temperature\*  $E_{kin} = \sum_{i=1}^{N} \frac{1}{2} m_i v_i^2 = \frac{3}{2} NkT$ 

Heat leaves system depending on how wrong temperature is

$$\frac{dT(t)}{dt} = \frac{T_0 - T(t)}{\tau_T}$$

- $T_0$  is reference temperature
- $\tau_t$  is a coupling / relaxation constant
  - $\tau_t$  tiny, heat moves fast.  $\tau_t$  big, ...
- to implement this idea? Multiply velocities

<sup>\*</sup>Slight simplification of formula

# Implementation of weak coupling

Scale velocities, 
$$v_{new} = \lambda v_{old}$$
 and  $\lambda = \left(1 + \frac{\Delta t}{\tau_T} \left(\frac{T_0}{T} - 1\right)\right)^{1/2}$ 

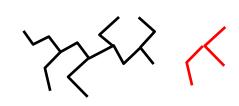

## Intuitively

- $\Delta t$  (time step) big ? temperature will change more
- what if  $T_0 = T$ ?
- square root?
  - wrong T reflects a difference in  $v^2$

### Can we break this?

- what if part is hot?
- it may remain hotter than black part

## Importance of heat baths

- Does not conserve energy In principle
- bring a system to equilibrium for temperature
   In practice
- avoid damage due to numerical errors / approximations
   For a system at equilibrium
- heat bath should do nothing

#### Does allow artificial tricks

- gently heat a system and watch behaviour
- gently cool a system and "anneal" it (more later)
- Extension to other properties
  - analogous reasoning for pressure bath

## **Summary of MD**

## Philosophy

natural way to copy/model/simulate nature

Lets one model processes in real time

MC	MD
• any cost/energy OK	requires continuous $E_{pot}(\mathbf{r})$
• time usually invalid	gives time scales
• most moves OK	physical trajectories
• Temperature enforced by	has explicit $E_{kin}$
acceptance	

both yield a Boltzmann distribution

both include entropy
