Classifying and comparing proteins

Plan

- why?
- domains
- classifications
 - hierarchical vs pragmatic / empirical
 - continuous or clustered?
- sequence similarity vs structure similarity
- example classifications
- comparison measures

Why?

Background – details later

- evolutionarily close proteins similar sequences
- evolutionarily remote proteins may have similar structures
- function prediction / annotation
- interpretation
- structure prediction can I predict this sequence fits to that structural class?

Examples..

Transfer of properties

Arguments as with homology

- Homology modelling
 - can I find a related protein?
 - can I say my protein has similar function / structure?
- Classifications of proteins
 - I have classes of proteins some members are well characterised
 - If you can say your protein is in class X,
 - probably has similar function to other members

Structure prediction

How many possible protein structures are there?

astronomical

How many interesting / different protein structures actually occur on earth?

• 2×10^3 to 5×10^3

de novo / ab initio prediction?

search in giant space

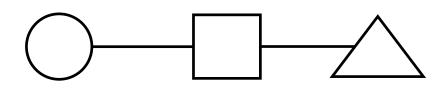

Find most likely protein fold?

- search amongst 10³ to 10⁴ structures
- find the class of your protein crude structure prediction

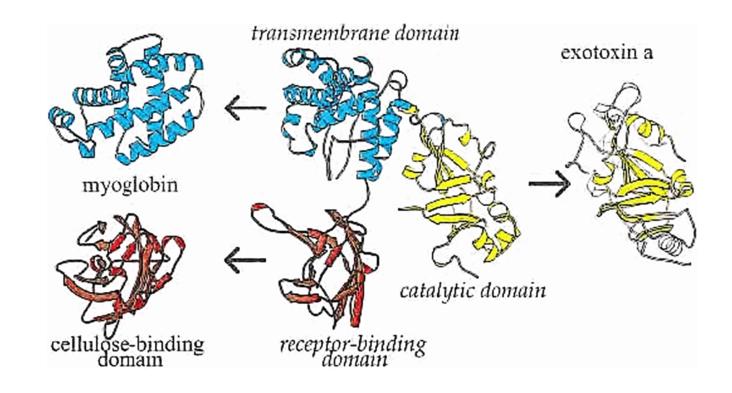

Domains

We will usually talk about protein domains (not whole proteins)

association of domains with function and evolution...

 most literature classifications work with domains

Domains for these lectures

Usually structure based

- compact units
- In these lectures
- no functional domains
- no sequence-based

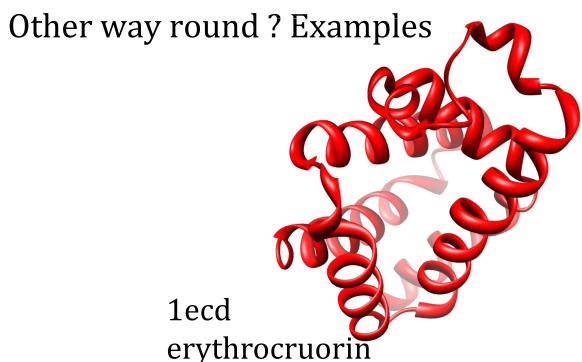

Should we classify by structure or sequence?

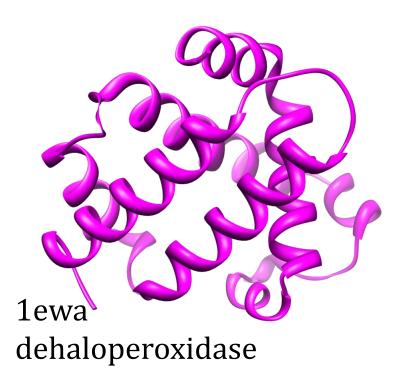

Structure vs Sequence similarities

More different than you might expect

Similar sequences

- have not diverged for too long
- expect similar structures

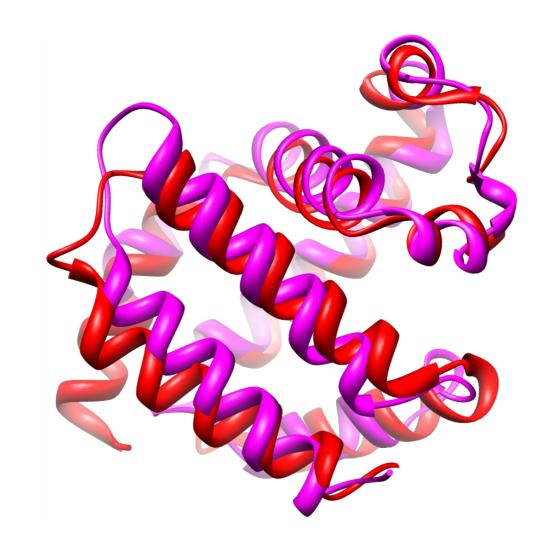

very different sequences

1ecd & 1ewa

- 17% sequence identity (very low)
- structures almost identical

Is this an exception?

- 100's of examples
- totally normal
- play with our server

http://flensburg.zbh.uni-hamburg.de/~wurst/salami/

Example family

Example, neighbours of 1cun chain A

• look at sequence identity (% id)

root mean square diff in Å

No	Chain	%id	lali	rmsd	Description
:	l 1cunA	100	213	0.0	ALPHA SPECTRIN
:	2 1hciA	24	111	1.6	ALPHA-ACTININ 2
;	3 1ek8A	12	106	4.4	RIBOSOME RECYCLING FACTOR
•	1 loxzA	9	91	2.5	ADP-RIBOSYLATION FACTOR BINDING PROTEIN GGA1
!	5 1eh1A	8	102	4.6	RIBOSOME RECYCLING FACTOR
	6 1hx1B	5	105	3.1	HEAT SHOCK COGNATE 71 KDA
•	7 1dd5A	8	103	4.7	RIBOSOME RECYCLING FACTOR
	3 11vfA	9	98	2.6	SYNTAXIN 6
	9 1bg1A	9	99	2.3	STAT3B
10	1hg5A	5	98	3.0	CLATHRIN ASSEMBLY PROTEIN SHORT FORM
1:	l 1hs7A	14	92	2.5	SYNTAXIN VAM3
1:	2 1dn1B	10	101	2.7	SYNTAXIN BINDING PROTEIN 1
1:	3 1ge9A	6	108	4.6	RIBOSOME RECYCLING FACTOR
1.	1 1fewA	8	125	3.5	SECOND MITOCHONDRIA-DERIVED ACTIVATOR OF
1!	5 1qsdA	4	90	2.4	BETA-TUBULIN BINDING POST-CHAPERONIN COFACTOR
	1e2aA	6	95	2.8	ENZYME IIA
alignment length 1	7 1i1iP	7	95	3.3	NEUROLYSIN
	3 1fioA	8	100	2.6	SSO1 PROTEIN
1:	9 1m62A	8	81	2.8	BAG-FAMILY MOLECULAR CHAPERONE REGULATOR-4
20	1k4tA	6	147	25.8	DNA TOPOISOMERASE I

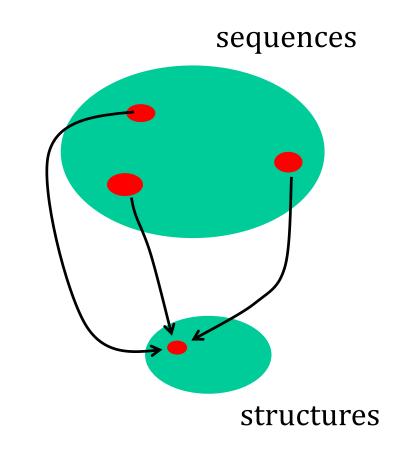

Structure vs Sequence

There are 1000's of such families

Summarise

- similar sequences
 - similar structures
- very different sequences
 - similar or different structures

why?

Structures < Sequences... Why?

Evolution

- many small changes
- if structure changes, function breaks, you die
- sequences change as much as possible within this constraint

Chemistry

- sequence determines structure
 - many sequences could fit structure (more next semester)

Surprising?

- consider near universal proteins
 - 100's millions years evolution, function largely preserved
 - sequence has changed radically

Classifying by sequence

Forget hierarchy (for now)

- tools any alignment program (blast, fasta, clustal, ...)
- method
 - survey all proteins in the protein databank
 - collect all pairs > x %

similarity	num clusters
90 %	44 029
70%	36 670
50%	29 339
nov	v 2018

- how many structure classes ? 2×10^3 to 5×10^3 ?
- some sequence classes are not really different from each other

Now.. examples of structure based classifications

Clusters and hierarchies

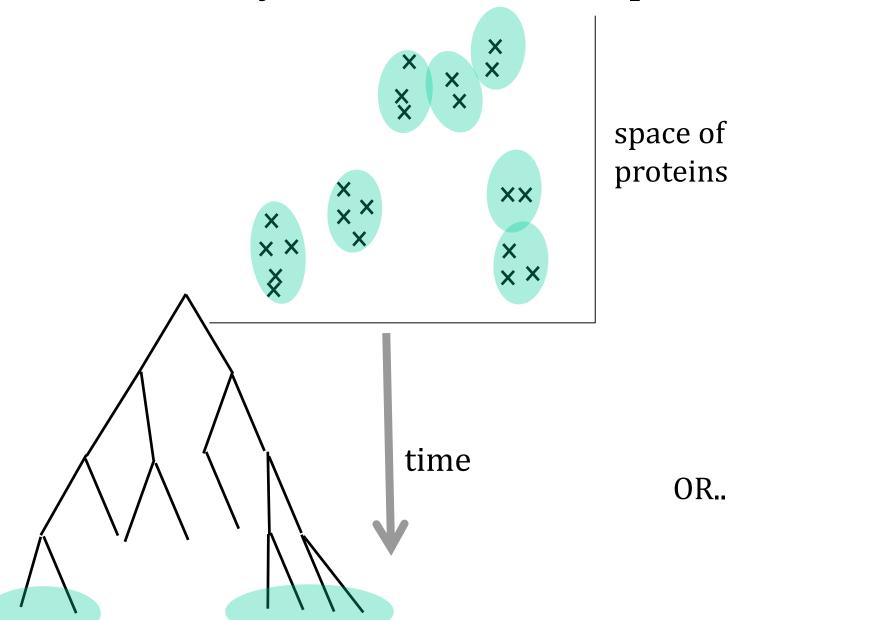

Are there clusters? Yes

- Sequence-based? Do a sequence search for a haemoglobin or profilin
 - find 10³ to 10⁴ homologues this is some kind of cluster
- Structure-based?
 - search for haemoglobins (or your favourite protein)
 - find $10^2 10^3$ similar structures a cluster

Are they hierarchical? No idea

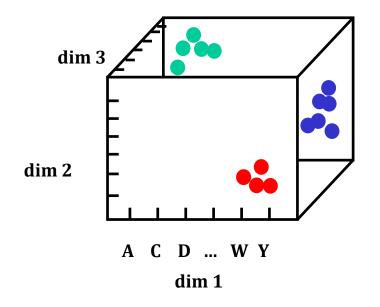

what is the question? (reminder from last lecture)

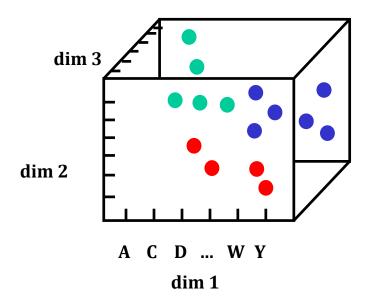

Maybe there should be protein clusters

If we knew every protein that every existed anywhere

would we be able to connect the clusters?

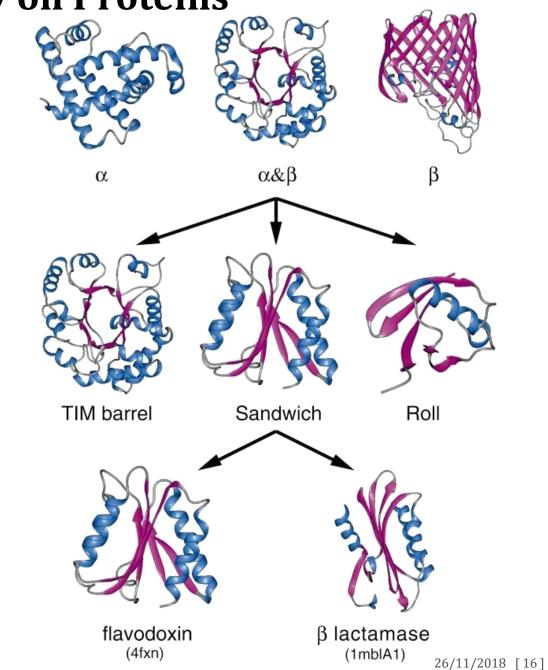

• An example of a hierarchical classification

Imposing a Hierarchy on Proteins

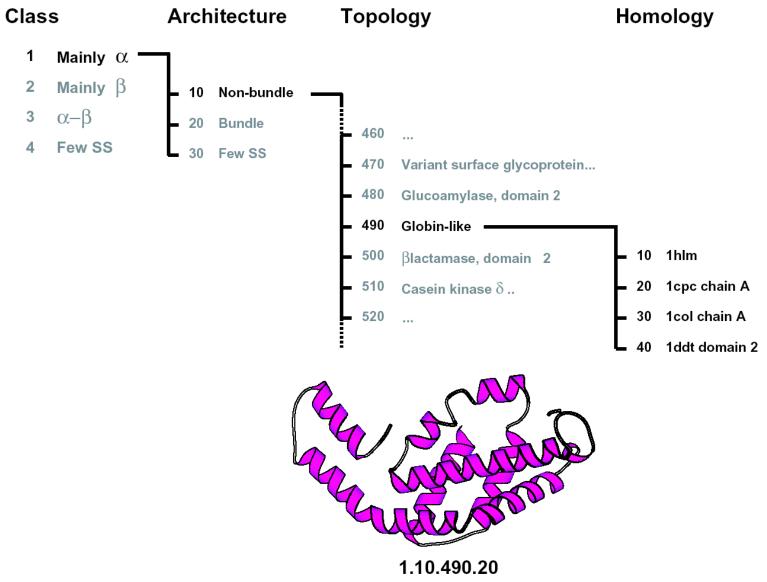

- parts may correspond to evolution
- top level?

How useful and applicable?

examples

Example from "CATH"

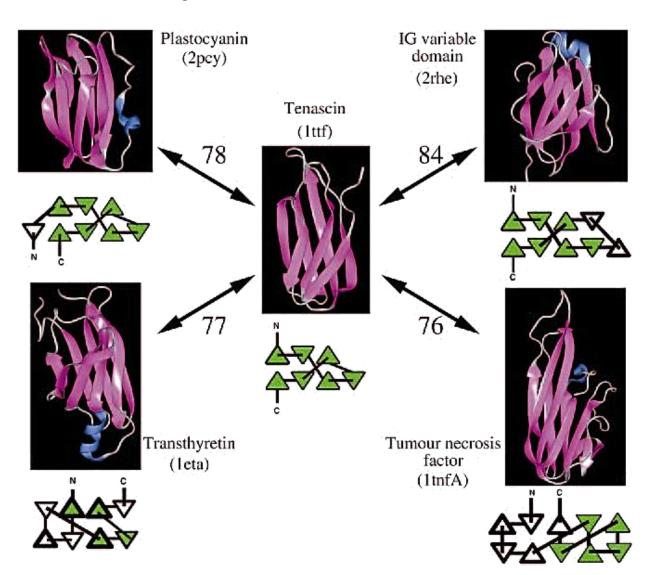

Mainly α .Non-bundle.Globin-like.1cpc chain A

Evolution and Classification

Can we interpret structures in evolutionary terms?

- sometimes
- for more remote proteinsnot really possible
- some typical figures from a literature classification

Lots of families

α -helix bundles?

- ≈226 domains,
- 3 % surveyed structures

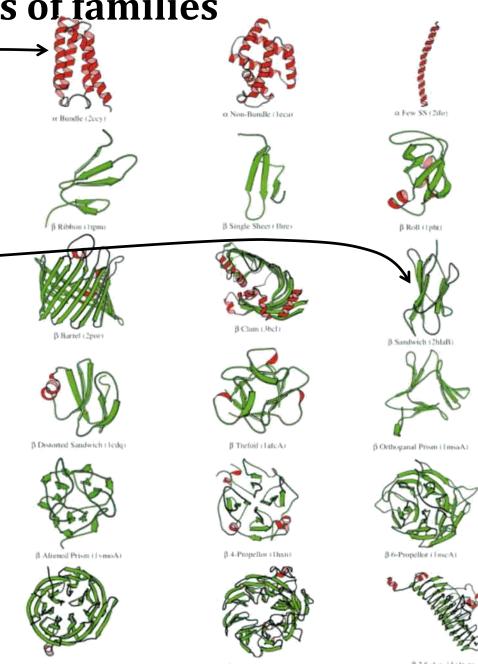

β-sandwich ≈1236 domains, 15 %

some families?

• < 0.01 %

Interesting...

some families very popular, some not

Some families populated more than others?

Are some structures more stable? physics?

Can some "accommodate" more sequences / tolerate more mutations?

next semester

Are some older in evolutionary terms?

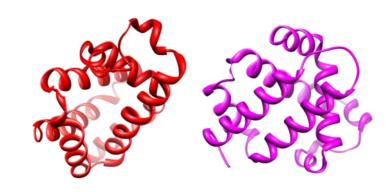

Biases? PDB has

- mainly soluble, globular proteins which crystallised
- few membrane-bound proteins

Hierarchy?

Is the hierarchy really justified?

- at low levels maybe
- at higher levels ? $(\alpha, \alpha/\beta, ..)$

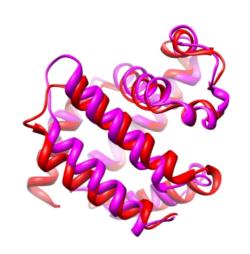

Better to discover relationships automatically

Imagine I can compare arbitrary proteins

- have some measure of similarity
- use this to classify

- proteins are different sizes and shapes
- how to compare?

Summary

- Classification would be useful
- Given a distance (dissimilarity) one can invent a space for sequences or structures
- not known if it
 - exists
 - is hierarchical
- sequence vs structure similarity
 - different sequences can fold to same structure
- imposing a hierarchy on protein structures very *ad hoc*
- one can forget hierarchy simply use a clustering method
 - one will need a measure of similarities
 - big topic...

FORGET HIERARCHIES

- forget evolution
- forget hierarchies
- just look for similarities

Protein Structure Comparison / Numerical

Common protein structural question

- how much has my protein moved over a simulation?
- how similar are these NMR models for a structure?
- how close is my model to the correct answer?

More difficult

how similar is rat to human haemoglobin?

Two cases

- 1. same protein, same number of atoms
- 2. different proteins

First

measures for easy cases

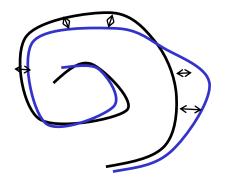

Numerical Comparison of Structures - Easy

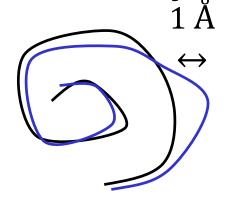

What units would we like?

- scale of similarity (0 to 1.0)?
- comparison of angles
- distance / Å? most common / easy to interpret

• consider analogy with standard deviation / variance

From Standard Deviation to RMSD

Analogy with comparing a set of numbers

- get average (mean) $\bar{x} = N^{-1} \sum_{i=1}^{N} x_i$
- standard deviation $\sigma = \left(N^{-1} \sum_{i=1}^{N} (x_i \bar{x})^2\right)^{1/2}$
- apply this to coordinates of r and r'

$$rmsd = \left(\frac{1}{N} \sum_{i=1}^{N} |\vec{r}_i - \vec{r}_i'|^2\right)^{1/2}$$

• rms / rmsd / RMSD = root mean square difference

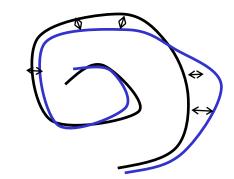

Calculating rmsd

$$rmsd = \left(\frac{1}{N}\sum_{i=1}^{N}|\vec{r}_i - \vec{r}_i'|^2\right)^{1/2}$$

start at one end

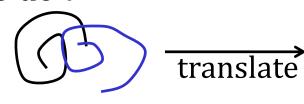

difference between pairs of atoms

$$|\vec{r}_i - \vec{r}_i'|^2 = (x_i - x_i')^2 + (y_i - y_i')^2 + (z_i - z_i')^2$$

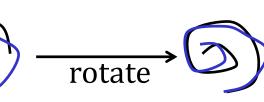

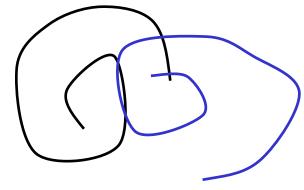

Problem..

- coordinates are normally...
 - what to do?

Translation and Rotation

translation

- c.o.m. = centre of mass $\vec{r}_{com} = \left(\sum_{i=1}^{N} m_i\right)^{-1} \sum_{i=1}^{N} \vec{r}_i m_i$
- subtract difference vector $\vec{r}_{diff} = \vec{r}_{com} \vec{r}'_{com}$ rotation
- rotation matrix to minimise

$$rmsd = \left(\frac{1}{N}\sum_{i=1}^{N}|\vec{r}_i - \vec{r}_i'|^2\right)^{1/2}$$

summary

- translate
- rotate
- apply formula

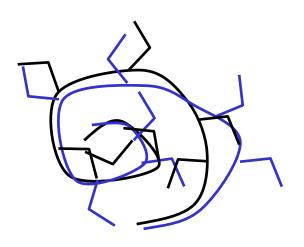

Still not finished

Which Atoms?

What tells me the shape of a protein?

- backbone trace
- What happens if you include all atoms?
- bigger *rmsd*
- normal choice
 - Cα
- sometimes
 - N, C^α, C
- all atoms?
 - when a model is very close

Still not finished with simple *rmsd*

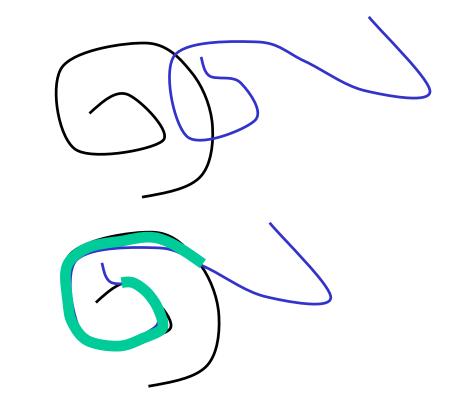

Parts Of Proteins

Two models of a molecule

- mostly very similar
- is *rmsd* a good measure?

Identify similar parts (method used in chimera)

```
define
```

```
superimpose ({r},{r'}, {d}) {
        translate ({r,},{r'}, {d})
        rotate ({r},{r'}, {d})
}
where {d} is some subset of sites
```

Selection of Interesting Atoms

Define a threshold like thresh = 2 Å ${d} = {|r_i - r'_i|} i=1..N$ sort {d} diff= rmsd $(\{r_i\}, \{r_i'\})$ while (diff > thresh) { remove largest d superimpose $(\{r\},\{r'\},\{d\})$ recalculate distances $diff = rmsd (\{r\}, \{r'\}, \{d\})$ if (diff < thresh)</pre> return {d}, diff else return broken Result? a subset of interesting atoms

26.11.2018 [31]

Subsets of Atoms

Originally, quantify structural differences as Å rmsd

Alternative quantity implied

number of residues used for rmsd below threshold

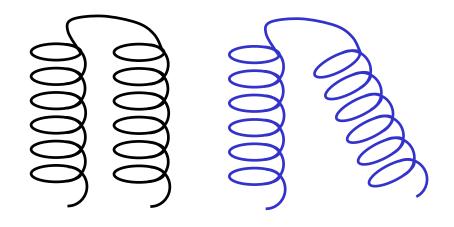

Implicit rule

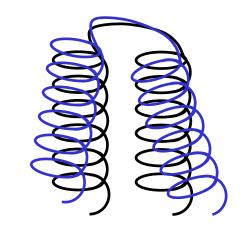

• as number of atoms \downarrow calculated $rmsd \downarrow$

Why not to use rmsd

Helices identical, fold identical

• *rmsd*?

• superposition requires rotation, affects all atoms

- big rmsd, but structure has hardly changed
- do not see that helices are identical
- more problems

Size dependence

Two proteins with 5 Å *rmsd* – similar or not?

Consider proteins of different sizes

- maximum difference with N_{res} = 50 or N_{res} = 100 ?
- consider random structures with N_{res} = 50 or N_{res} = 100
- for small proteins 5 Å *rmsd* may be bad
- for large proteins 5 Å *rmsd* may be almost identical

extends to comparisons of small molecules

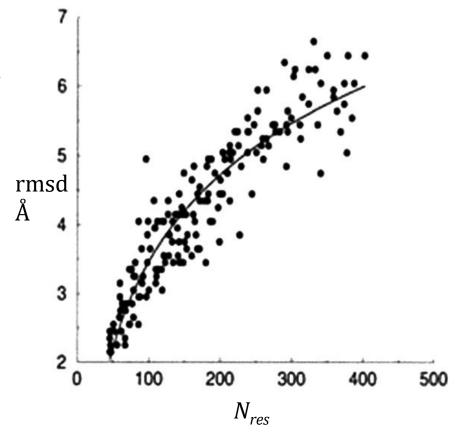

• ligands / medikamente...

What would one expect for random structures ?...

Size dependence

Empirical

survey of random protein comparisons

Theoretical

can find result from compact polymer theory (Florey)

not in these lectures

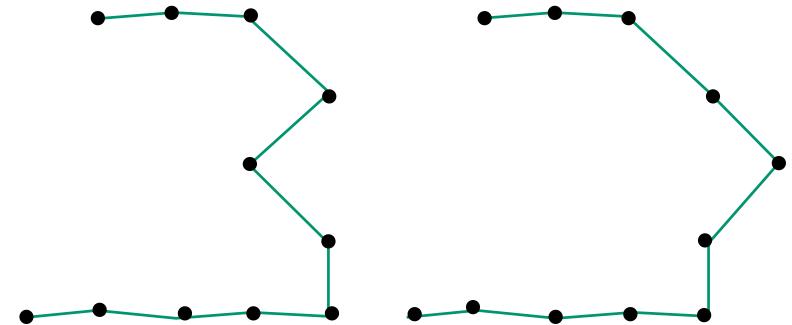

rmsd size dependence

good rule

• $rmsd_{interesting} = a + b(N_{res})^{1/3}$ for some constants a, b

problems with *rmsd* measure – alternatives

• angles ? OK – angles compensate for another

distance matrices ...

Distance Matrices With Numbers

Another characteristic of structures

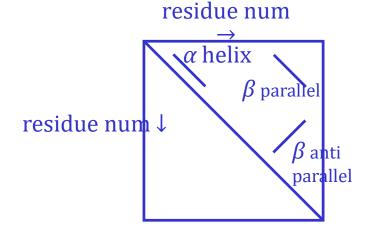

- C^{α} distance matrices
- measure the distance between C^{α} atoms

	1	2	3	4	5	6	7			N
1	0	3.8	6	7						
2		0	3.8	5						
3			0	3.8	4.5					
4				0	3.8					
5					0	3.8				
6						0	3.8			
7							0	3.8		
								0	3.8	
									0	3.8
N										0

Distance Matrix for Recognizing Structure

One way to summarise a structure

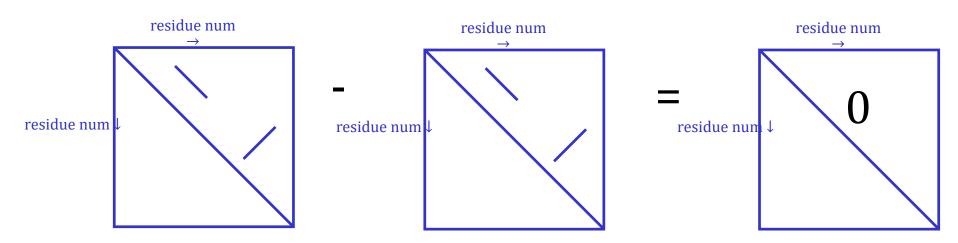

- plot C^{α} distance matrix, points below 4 Å
- can make α -helices and β -sheets clear

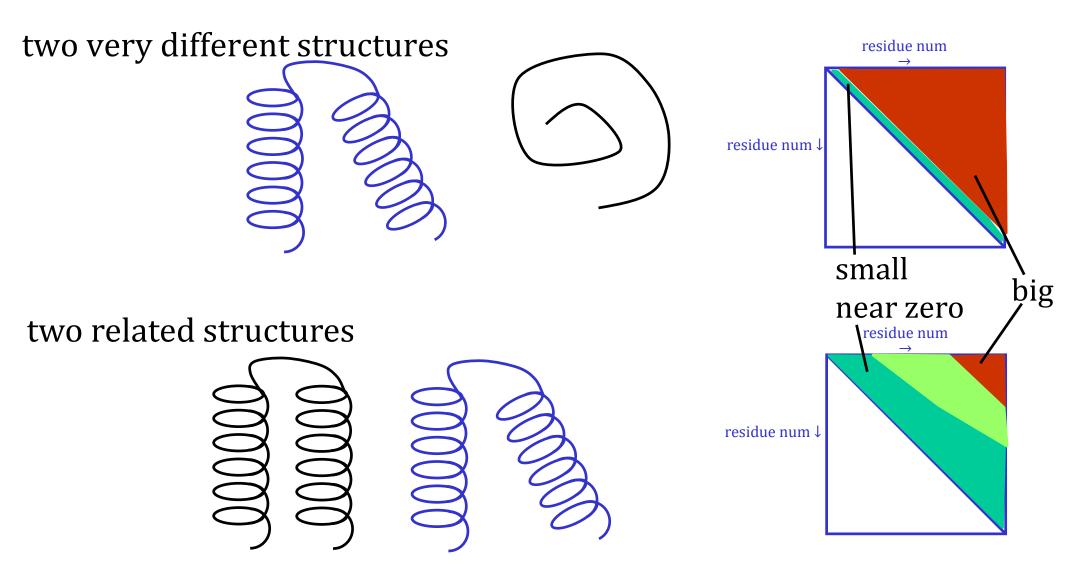

Distance matrix for comparing structures

Take two similar proteins

look at the difference of distance matrices

Comparing Distance Matrices

pictures are better than any single measure, but...

From Distance Matrices to Single Number

For lots of comparisons, single number is more convenient

Root mean square (rms) difference of distance matrices

• distance between C^{α} atoms i and j $d_{ij} = |\vec{r}_i - \vec{r}_j|$

rms of distance matrices measure is

$$rms = \left(\frac{2}{N(N-1)} \sum_{i=1}^{N} \sum_{j>i}^{N} (d'_{ij} - d_{ij})^{2}\right)^{1/2}$$

Like all other *rms* quantities

normalised over top half of matrix

Summary - Comparing Models / Structures

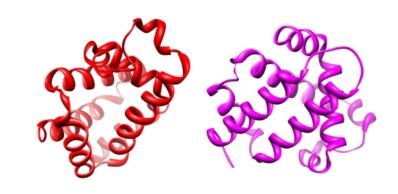

- rmsd
 - most popular
 - requires superposition (translate + rotate)
 - can be fooled by "hinge" movements
 - size dependent
- to look at the shape of a molecule use C^{α} or backbone atoms
- numbers in Å have a physical meaning
- to look for the common core of a structure, find a subset of backbone
- other measures may be better than rmsd
- weakness of all measures
 - a single number can never capture all information

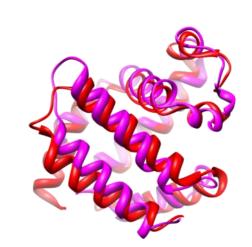

Comparing Proteins – different sizes

- compare red and blue proteins
- if we know which residues match
 - easy (use any rms formula)
- which residues match?
 - sequence alignment?

```
protein 1 A C D W Y T R P K L H G F D S A C V N protein 2 A C D W W T - P K V H G Y D S A C V N
```

- green residues mismatches (no problem)
- blue residues ignore
- is this useful for similar proteins? very (rat vs human haemoglobin)
- for very different proteins? no

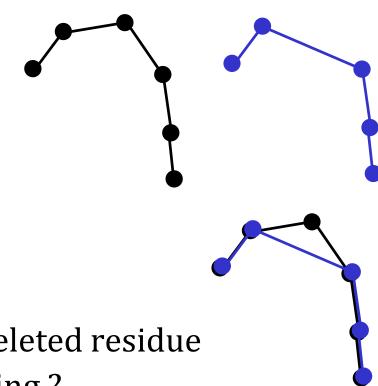

Comparing Very Different Proteins

Sequence alignment vs identity

- as identity ↓, errors ↑
- Consequence
- methods needed
 - operate on C^{α}
 - do not require sequence

How difficult?

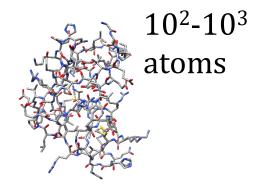

- superposition requires recognising the deleted residue
- can we use standard dynamic programming?
 - no
- gap/insertion at any position, any length
 - combinatorial explosion

Strategies For Comparing Different Structures 1. use secondary structure

Combinatorial explosion is the problem

- reduce size of problem
- use elements of secondary structure

about 6 units

- define secondary structure
- search for superposition
- for each residue
 - find closest C^{α} in partner structure
 - use the set of matching residues to calculate *rmsd*

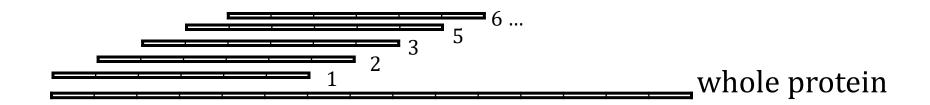

PDB code 3i4o

2. Peptide fragment strategy

- more general version of idea on previous page
- basis of most popular methods

Ingredients

- break protein into overlapping fragments of structure (length 6 or 8)
- protein is no longer a string of residues nor a whole structure

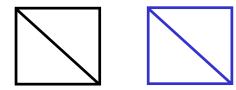

• each fragment is a little distance matrix

Fragment Based Comparison

any two distance matrices can be compared

• two proteins length *N* and *M* can now be compared...

protein 1 fragments →

protein 2 fragments↓

	1	2	3	4	5			<i>N</i> -7
1	1.3	1.0	2.0	0.9				
2	2.7	2.3	0.5					
3	5.5	4.4	•••					
4	0.1	0.5	0.3	3.3	4.2	•••		
5	1.9	4.4	5.5	0.3	3.3	•••		
6	4.4	1.6	1.7	5.0	2.3	•••		
	4.1	3.1	3.3	4.4	0.2	3.3		
<i>M</i> -7	5.2	1.1	0.1	5.5	4.4	0.1	3.3	0.1

- imagine rmsd
- this is now like a sequence comparison problem

Finding Equivalent Fragments

- find optimal path through matrix
- classic dynamic programming method like sequence comparison

	1	2	3	4	5			N-7
1	1.3	1.0	2.0	0.9	•••			
2	2.7	2.3	0.5					
3	5.5	4.4	•••					
4	0.1	0.5	0. %	3.3	4.2	•••		
5	1.9	4.4	5.5	<i>%</i>	3.3	•		
6	4.4	1.6	1.7	5.0	23	•••		
	4.1	3.1	3.3	4.4	0.%	3.3	•••	
N-7	5.2	1.1	0.1	5.5	4.4	0.1	3.3	0.1

Like sequence comparison

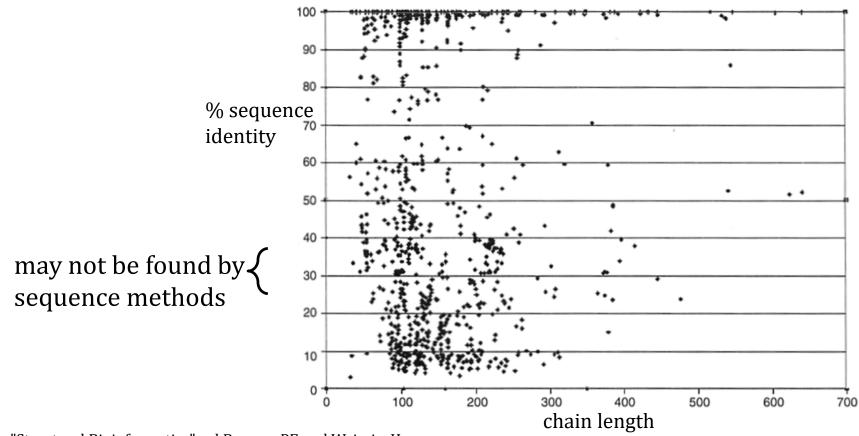

- find optimal path through matrix
- classic dynamic programming method (N & W, S & W)
- uses gap penalties

Comparing Different Size Protein Structures

- Break protein into overlapping fragments
- fragments can be compared to each other via distance matrices
- align like sequences
- from aligned fragments, get list of aligned residues
- using aligned residues, calculate *rmsd*, *rms* of overall distance matrices

How Important Are These Similarities?

- survey 1 000 proteins
- find structurally similar pairs
- plot sequence identity

Summary of All Protein Comparisons

Classification of proteins

- could be done by sequence, better by structure
 Structure comparison
- for one protein
 - selection of atoms
- for different proteins
 - requires list of matching atoms
- for similar proteins
 - can use pairs from sequence alignment
- for often dissimilar proteins
 - pure structure based method

Summary of everything

- classification is appealing
- very different answers using sequence or structure
- even if we believe in evolution
 - complete hierarchical scheme may be artificial
